1. INTRODUCTION

Under contract to Applied Marine Sciences, Pacific Eco-Risk Laboratories performed sediment toxicity testing on 20 marine sediment samples, collected from the Outer Cook Inlet and Shelikof Strait during the period of July 9-16, 1997. These sediment toxicity evaluations consisted of performing the U.S. EPA's 10-day estuarine amphipod survival test with the amphipod *Eohaustorius estuarius*.

This report describes the performance and results of these sediment tests.

2. SEDIMENT TOXICITY TESTING

The methods used in conducting these tests followed the guidelines established by the EPA manual "Methods for measuring the toxicity of sediment-associated contaminants with estuarine and marine amphipods" (EPA-600/R-94/025, U.S. EPA, Env. Research Laboratory, Narragansett, RI).

2.1 RECEIPT AND HANDLING OF THE SEDIMENT SAMPLES

During the period of July 9-16, 1997, grab samples of marine sediments of approximately 2 L volume were collected from each of 20 sites within the Outer Cook Inlet and Shelikof Strait; these samples were collected into 2 L high-density polyethylene bottles, and were then shipped, via overnight delivery, to the testing laboratory in Martinez, CA, where they were received on July 22, 1997. Upon receipt, the sediment samples were stored at 4°C until used to set-up the test replicates for the sediment toxicity tests on July 23, 1997.

2.2 TEST ORGANISMS

The *Eohaustorius estuarius* used in these tests were obtained from a commercial supplier (Northwestern Aquatic Sciences, Newport, OR). These organisms were acclimated to a salinity of 27 ppt prior to shipment to the testing lab; upon receipt, the test organisms were acclimated to the test salinity of 34 ppt.

2.3. SEDIMENT TOXICITY TESTING PROCEDURES

The sediment toxicity test replicates were established on July 23, 1997. There were 4 replicates for each site. Each replicate consisted of a 1 L glass beaker to which approximately 175 ml (approximately 2 cm depth) of sediment was added (each sediment sample was homogenized prior to loading of the test replicate containers). Test replicates were similarly established for the Control treatment, which consisted

of the same sediment from which the test organisms were originally collected; this sediment was a fine-grained sand-silt mixture very similar in grain size characteristics to the site sediments. The overlying water consisted of 0.45-µm filtered seawater (collected from the U.C. Bodega Bay Marine Laboratory); approximately 800 mL of this water was carefully poured into each test replicates so as to minimize disturbance of the sediment. These test replicates were then placed in a temperature-controlled water bath at 15°C under continuous illumination from fluorescent lighting. Each test replicate was gently aerated.

The following day (July 24, 1997), routine water qualities (temperature, pH, dissolved oxygen (D.O.), and salinity) were determined for each test replicate. Then, the tests were initiated with the random allocation of 20 randomly-selected *Eohaustorius*, 3-5 mm in length, into each replicate container (aeration was shut off until the amphipods re-buried themselves, approximately 1 hr after their introduction). Each day, for the next 10 days, the temperature, pH, D.O., and salinity of the overlying water were measured in one test replicate for each treatment. On Days 2 and 8, a small sample of the overlying water was collected from each replicate for each treatment, composited, and analyzed to determine the total ammonia at that treatment.

After 10 days exposure, routine water qualities (temperature, pH, dissolved oxygen (D.O.), and salinity) were again determined for each test replicate. Then, the contents of each replicate beaker were sieved and examined, and the surviving amphipods were collected and counted. The resulting % survival data were statistically analyzed using the Tox-Calc statistical software (TidePool Scientific, McKinleyville, CA). Comparison of the survival data from each of the sites with the Control treatment was made using the Homoscedastic t-Test. The results of these tests are summarized in Section 3.

3. RESULTS

The results of the toxicity evaluation of these 20 sediments are summarized below in Table 1. Briefly, there was 96.25% survival of the amphipods in the Control sediment. Statistical comparison of amphipod survival at the site sediments with the Control were made using the Homoscedastic t-Test; these analyses indicated that amphipod survival in 15 of the site sediments were significantly less than the Control at $p < 0.05$.

Copies of summary of statistical analyses for each of the 20 tests are provided in Appendix A. Copies of the test data sheets are provided in Appendix B.

Table 1. Percent survival of <i>Eohaustorius estuarius</i> in the test sediments.					
Sediment Site	% Survival in Test Replicates				Overall Mean % Survival
	Rep A	Rep B	Rep C	Rep D	
Control	95	100	90	100	96.25
